# Rotating pipe: Test case description

## Flow parameter

- Laminar flow  $Re = 500$  (based on diameter and inlet bulk velocity)
  - Fully developed laminar inlet (parabolic profile)
- Middle section rotating at rotation rate  $\alpha = V_{\theta}/U_B = 2.5$

## Calculations definition

- Single domain with imposed wall velocity
- Code-Code coupling with 3 instances and sliding plane
  - Mesh rotation
  - Coriolis source force
- Turbo-machinery module with mesh joining
  - Mesh rotation and gluing at every time step
  - Coriolis source force with mesh joining at the start of the simulation
- Mesh with 256 cells in the cross section for 56 planes in the streamwise direction, for total length of  $5D$

Line  $x=0.25$

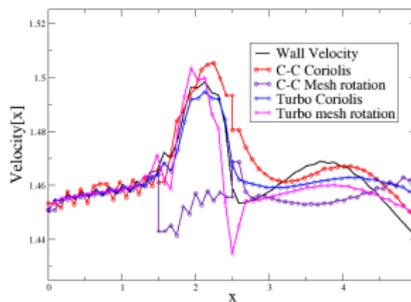

Line  $x=0.45$

# Comparison: Profiles along flow direction

Line x=0

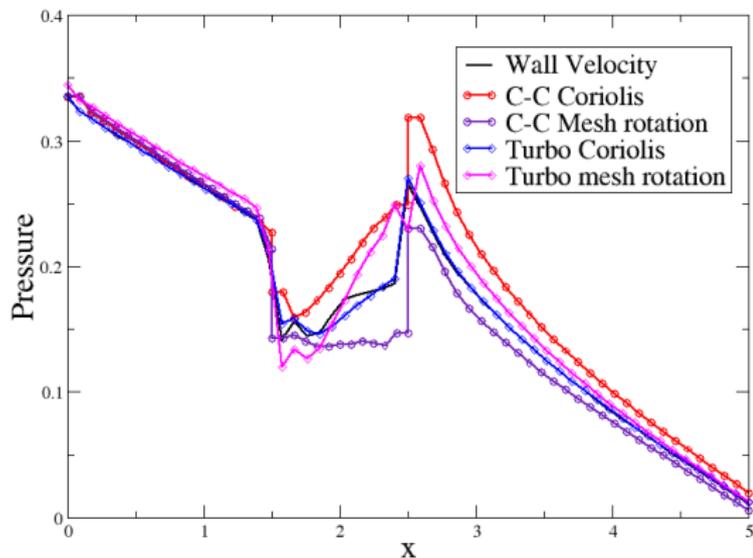

- C-C coupling with mesh rotation less sensitive to the rotation
- Turbo module with mesh rotation enhance the effect of the outlet interface
- Turbo module with frozen rotor is the closest to the imposed wall velocity
- Both methods with mesh rotation show fluctuations up-stream and in the rotor

- 2 *Code\_Saturne* in-situ visualization (B. Lorendeau)

## Integration of Catalyst into Code\_Saturne

- Tightly coupled solution
- Designed for tackling bad I/O performances
- Allows users to visualize their data at simulation-time

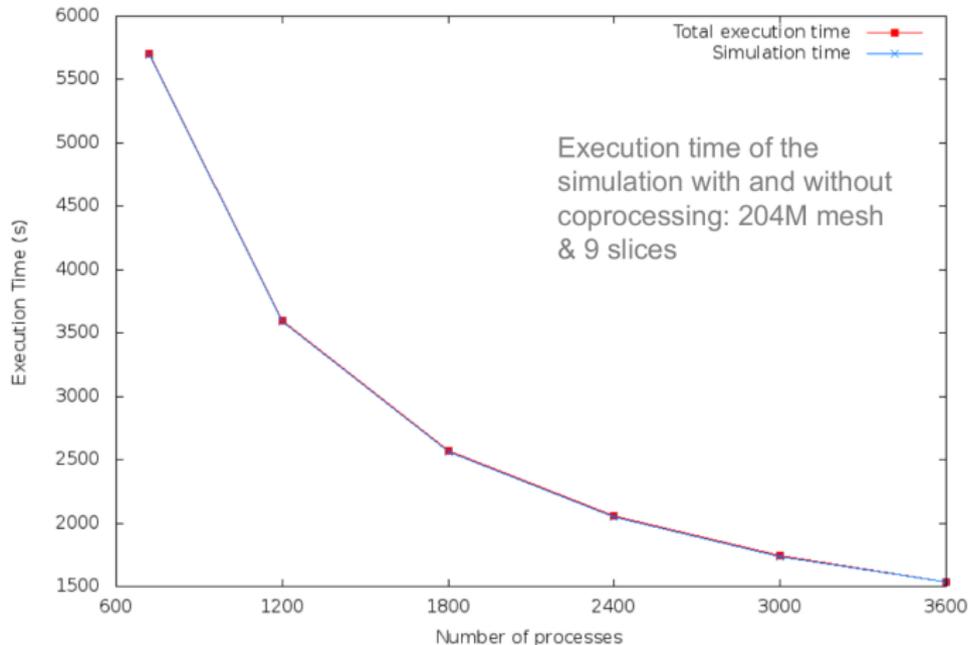

Play the video

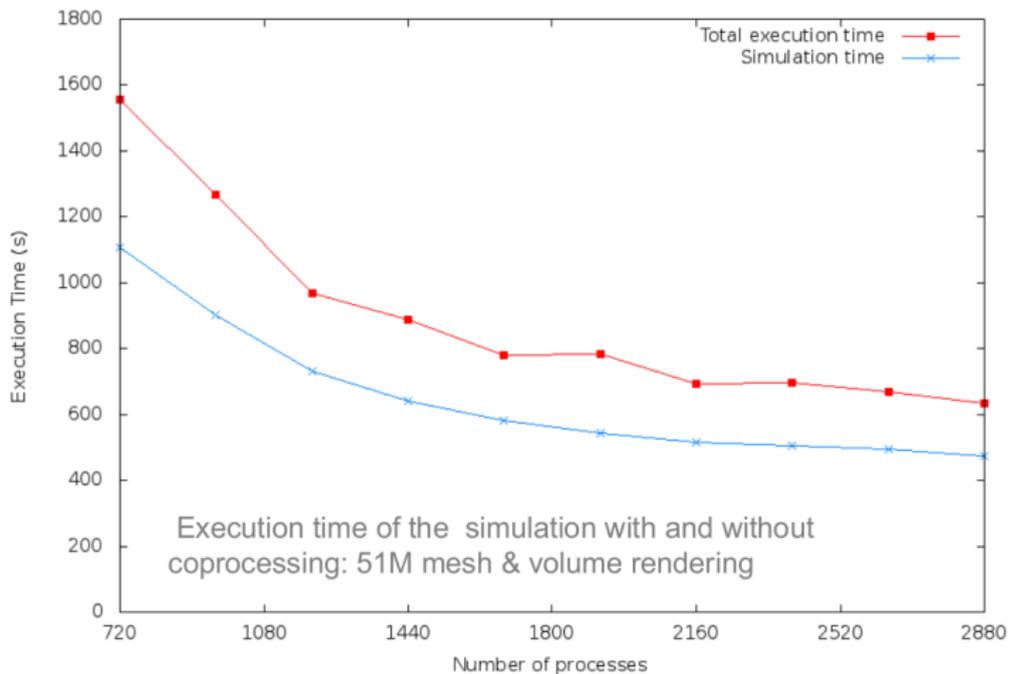

## Advantages

- Faster simulation
- Video generation
- Reduction of data volume
- Visualize during simulation

## Downsides

- Not for exploration
- Limited Interactivity
- Memory usage

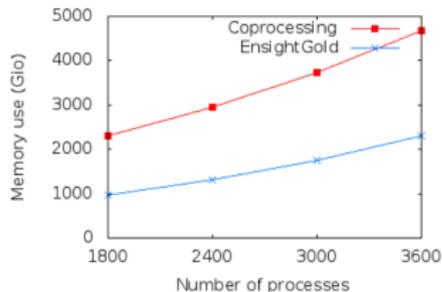

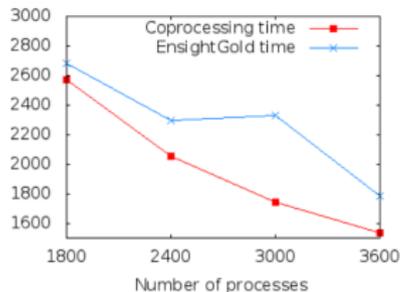

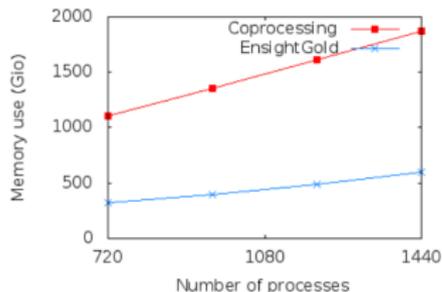

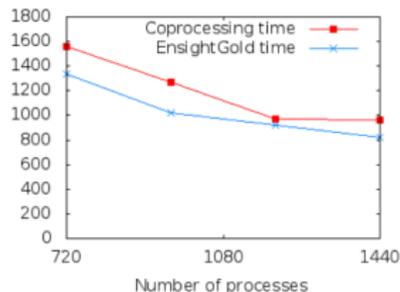

- Size: 204M  
&  
- 9 Slices

Execution Time (s)

- Size: 51M  
&  
- Volume Rendering

Execution Time (s)

## Integration of Catalyst into Code\_Saturne

- Makes simulation and visualization works together
- runs a pre-defined VTK pipeline on the simulation data
  
- Scaling and processing time very satisfactory
- Memory management being optimized
- Further tests on BlueGene Q with 500 millions of hexaedrons
- Further tests on the Live Visualization
